Cardiomyopathy/Dysplasia Bandar Al-Ghamdi,2017 Arrhythmogenic right ventricular cardiomyopathy dysplasia ARVC D is a rare disease characterized by progressive fibrofatty replacement of the myocardium primarily involving the right ventricle RV The structural changes in the ventricular myocardium form a substrate for ventricular arrhythmia ranging from

premature ventricular complexes to ventricular tachycardia typically of RV origin and may result in RV failure and progress to congestive heart failure at a later stage ARVC D is a recognized cause of sudden cardiac death in young people but it may occur at any age With the discovery of underlying pathogenic mutations involved in the disease development and insight from long term follow up of ARVC D patients ARVC D is an inherited cardiomyopathy Mutations in at least eight genes have been involved in ARVC D genesis in 30 50% of patients Most of these genes are involved in the function of desmosomes which are structures that attach heart muscle cells to one another Desmosomes provide strength to the myocardium and play a role in signaling between neighboring cells Mutations in the genes responsible for ARVC D often impair the normal desmosomal function There has been significant advancement in the diagnosis and management of ARVC D in the past few decades This chapter provides an overview of ARVC D pathophysiology clinical presentations diagnosis and management **Clinical**

Molecular Genetics of Cardiac Electrophysiology C. Berul, Jeffrey A. Towbin, 2000-04-30 The molecular basis for atrial fibrillation continues to be largely unknown and therapy remains unchanged aimed at controlling the heart rate and preventing systemic emboli with anticoagulation Familial atrial fibrillation is more common than previously suspected While atrial fibrillation is commonly associated with acquired heart disease a significant proportion of individuals have early onset without other forms of heart disease referred to as lone atrial fibrillators It is also well recognized that atrial fibrillation occurs on a reversible or functional basis without associated structural heart disease such as with hyperthyroidism or of atrial fibrillation following surgery It remains to be determined what percentage in these individuals is familial or due to a genetic predisposition Mapping the locus for familial atrial fibrillation is the first step towards the identification of the gene Isolation of the gene and subsequent identification of the responsible molecular genetic defect should provide a point of entry into the mechanism responsible for the familial form and the common acquired forms of the disease and eventually provide more effective therapy We know that the ionic currents responsible for the action potential of the atrium is due to multiple channel proteins as is electrical conduction throughout the atria Analogous to the ongoing genetic studies in patients with familial long QT syndrome it is highly likely that defects in each of these channel proteins will be manifested in familial atrial fibrillation
