In order to tackle the computer challenge we will need an algorithm A collection of instructions that must be carried out in order to transform an input into an outcome is referred to as an algorithm One illustration of this would be the development of an algorithm to produce a classification Your ordered list is the result and the input is a series of numerical values to be arranged You might be interested in discovering the most effective algorithm which either needs fewer instructions or less memory or both and you might discover that there are numerous algorithms for the same work On the other hand we do not have an algorithm for certain tasks such as determining what constitutes spam and what constitutes legitimate e mail We are aware of the nature of the entry which is a simple typeface file contained within an email document We are aware of the expected outcome which is a yes no answer signifying whether or not the communication should be considered spam We are not familiar with the process of converting information to output The definition of what constitutes spam shifts over time and differs from one individual to the next Using statistics we are able to compensate for our dearth of understanding We are able to quickly collect thousands of example messages some of which we are aware are spam and would like to learn more about how they are constructed Therefore we would like the computer machine to automatically determine the procedure that should be used for this work There is no need for you to learn how to arrange numbers because we already have algorithms for that however there are many applications with example data that do not require an algorithm Because of developments in computer technology we are now able to store and analyze large quantities of data as well as retrieve this data from geographically dispersed locations through the use of a computer network Most data acquisition instruments today are computerized and capture accurate data
