**Abstract** We introduce blind channel identification and equalization for orthogonal frequency division multiplexing (OFDM) system without using a guard interval (GI). Inter-symbol-interference (ISI) is significantly reduced by truncation method. To perform channel identification, Subspace and Maximum Likelihood methods are proposed. To achieve enhanced performance and robustness to channel frequency nulls, receiver diversity and OFDM is combined. The performance of the proposed system is illustrated by computer simulations.

**Index Terms:** OFDM, channel identification, equalization, GI-less.

## I. INTRODUCTION

Orthogonal Frequency Division Multiplexing (OFDM) is a multi-carrier digital modulation technique that facilitates the transmission of high data rates with a limited bandwidth [14], [15]. It is an effective technique for several applications such Digital Audio Broadcasting (DAB) and terrestrial Digital Video Broadcasting (DVB) [13]. In addition, OFDM forms the basis for the physical layer in upcoming standards for broadband Wireless Local Area Network (WLAN) [10], i.e. IEEE 802.11a and Multimedia Mobile Access Communication Systems (MMAC) and for Fourth Generation (4G) broadband wireless systems that will perform multimedia transmission to mobiles and portable personal communications devices, i.e. European MEMO project and for IEEE 802.16.

Due to the increase in the delay spread, multipath fading has become a major concern as systems with high data rate are more liable to Inter-symbol-interference (ISI). Classically, ISI is eliminated by employing a cyclically extended time domain guard interval (GI). Thus, each OFDM symbol is preceded by a periodic extension of the symbol itself. This GI is also known as cyclic prefix (CP) and the system CP-OFDM [4]. Recently, zero-padding OFDM (ZP-OFDM), which pre-pends each OFDM symbol with zeros rather than replicating the last few samples, has been proposed [3], [4]. ZP-OFDM not only has all the advantages of CP-OFDM, but also guarantees symbol recovery and ensures finite impulse response (FIR) equalization. However, the implementation of a ZP-OFDM system involves transmitter modifications and complicates the equalizer.

However, due to extra symbols required by the GI, the OFDM spectrum is underutilized. This overhead can be significant for channels for short latency OFDM systems. For example, in wireless ATM network demonstrator (WAND), one of the projects is HiperLAN [8], the efficiency of bandwidth usage is only 66.67%, indicating a significant loss in utilization.

In this paper, we develop blind channel identification and equalization for GI-less OFDM system, which do not use a CP (or GI). The channel identification are developed based on Subspace (SS) [11], [1] and Maximum Likelihood (ML) techniques [9], [7], [5].

Some notations are used throughout the paper. Superscripts  $T$  and  $H$  stand for transpose operator and Hermitian operator, respectively and  $*$  stands for linear convolution.

## II. DATA MODEL

Fig. 1. GI-less OFDM system: transmitter and receiver.

Figure 1 shows the concept of the proposed OFDM-based SIMO system whose transmitter has single antenna and receiver has multiple antennas. In a baseband GI-less based SIMO system, the transmitted symbols are parsed into blocks:  $\mathbf{x}_k = [x_k(0), x_k(1), \dots, x_k(N-1)]^T$ , where  $k = 1, 2, \dots, K$ . The elements of  $\mathbf{x}_k$  are considered to be independent and identically distributed (i.i.d.). We regard these elements to be in the frequency domain. We assume perfect synchronization between symbols. The symbol block  $\mathbf{x}_k$  is then modulated and converted into the time domain by the IFFT matrix  $\mathbf{F}_N^T$ , where  $\mathbf{F}_N = [\mathbf{F}_0, \dots, \mathbf{F}_{N-1}]^T$  stands for the size  $(N \times N)$  with entries  $f_{n,k} = \frac{1}{N} \exp(j \frac{2\pi n k}{N})$  where  $k, n = 0, \dots, N-1$ .

Let  $\mathbf{H}_0$  be the  $qN \times N$  block lower triangular Toeplitz matrix with first block-column  $[\mathbf{h}^T(0), \dots, \mathbf{h}^T(L), \mathbf{0}^T, \dots, \mathbf{0}^T]^T$  and  $\mathbf{H}_1$  be the  $qN \times N$  block-upper triangular Toeplitz matrix with first block-row  $[\mathbf{0}, \dots, \mathbf{0}, \mathbf{h}^T(L), \dots, \mathbf{h}^T(1)]$ . For later reference, we define  $M = N - L$ ,  $n = qN$ ,  $m = qM$ ,  $\lambda = qL$ , and  $\phi = q(L+1)$ . Then, in a noisy environment the relation between the transmitted and the

Principles of Signal Detection and Parameter Estimation Bernard C. Levy, 2008-12-16 As a discipline signal detection has evolved significantly over the last 40 years. Some changes have been caused by technical advances like the development of robust detection methods or the use of the theory of large deviations to characterize the asymptotic performance of tests but most changes have been caused by transformations in the engineering systems to which detection techniques are applied. While early applications of signal detection focused on radar and sonar signal processing or the design of digital communication receivers, newer areas of application include image analysis and interpretation, document authentication, biometrics, and sensor or actuator failure detection. This expanded scope of application has required some adjustment in standard ways of formulating detection problems. For example, image processing applications typically combine parameter estimation and detection tasks so the separation of parameter estimation and detection in distinct operations typical of early communication systems where parameter estimation was accomplished through the use of training signals needs to be abandoned. Other changes have occurred in the design of communication systems which make it increasingly difficult to treat the detection of communications signals and of radar/sonar signals in a unified manner. This common framework assumes implicitly that intersymbol interference is not present and that channel coding and modulation are implemented separately since in this case modulated signals can be detected one symbol at a time. But modern communication systems are typically designed to operate over bandlimited channels where intersymbol interference is present and starting with the introduction of trellis-coded modulation, modulation and coding have become intertwined.
