Gibson,1972 Noise measurements were obtained on models of jet augmented lift systems which are currently being considered for use on proposed short takeoff and landing vehicles These configurations included a conventional internally blown flap an augmenter wing an externally blown flap and modifications of these basic concepts The tests were conducted in the Langley anechoic noise facility at zero forward speed with cold air jets The conventional internally blown flap exhibited lower noise levels than the augmenter wing and the externally blown flap at the same pressure ratios being of the order of 8 dB or more at the lowest pressure ratio and of the order of 20 dB at the highest pressure ratio of the tests The data also indicated that for the conventional internally blown flap

there may be an optimum gap size other than zero between the turning lip and the flap leading edge from the standpoint of minimum noise generation or admittance Increasing the trailing edge thickness of the plain internally blown flap produced no appreciable change in the overall sound pressure level or frequency spectral content in the range of the tests The data indicated that at a position on the ground directly under the jet exit the externally blown flap and the augmeter wing overall noise levels are comparable to each other throughout the pressure range of the tests United States Census of Manufactures, 1954, 1957
