Construction and utilization of digital twins for personalized therapeutic predictions Samuel Schäfer,2024-10-18 Modern

healthcare faces a significant challenge namely that 25 70% of patients with common diseases do not benefit from standard treatments despite the availability of over 13 000 drugs registered in DrugBank This discrepancy is likely due to these diseases complex and heterogeneous molecular nature rather than a lack of therapeutic options Emerging technologies have revealed the immense molecular complexity underlying common diseases For instance singlecell RNA sequencing scRNA seq has demonstrated altered gene interactions in and across multiple cell types in numerous tissues Furthermore these technologies have revealed vast molecular differences between patients with the same diagnosis There is a wide gap between this complexity and the current diagnostic and therapeutic approaches Aim To bring personalized medicine one step closer to the clinic this thesis focuses on developing digital disease models that can capture the molecular biological complexity of disease in individual patients We aim to harness these disease models to identify optimal treatments for each individual patient Paper I We started by exploring the usefulness of OMIC based approaches for diagnostic and therapeutic predictions Utilizing a single cell RNA sequenced mouse model of antigen induced arthritis we aimed to prioritize cell types and therapeutic targets Initial pathway enrichment analyses did not yield relevant prioritization prompting an investigation into network based approaches Multi cellular disease models MCDMs for AIA and human rheumatoid arthritis were constructed incorporating predicted cell type interactions Centrality analysis indicated that these interactions could quantify a cell type s relative importance in disease pathogenesis We hypothesized that transcriptomic alterations in central cell types might reflect the MCDM serving as potential diagnostic markers An analysis of CD4 T cells from patients with 13 different inflammatory diseases and healthy controls demonstrated that these profiles could discriminate between healthy and diseased states and among diseases Furthermore a network based approach identified drugs targeting disease associated changes common to multiple inflammatory diseases Notably one of these drugs bezafibrate successfully dampened inflammation in the AIA mouse model Paper II Building on the insights from Paper I we investigated multicellular network models MNMs with time as an additional dimension Using seasonal allergic rhinitis SAR as a disease model we analyzed time series scRNAseq data to construct MNMs of inflammatory diseases We identified thousands of disease associated expression changes across multiple cell types varying at different disease stages Notably upstream regulators URs of these changes were also stage dependent and multidirectional To prioritize URs for drug discovery we focused on those causing significant expression changes in multiple cell types across all time points This strategy was validated through similar analyses of atopic dermatitis ulcerative colitis and Crohn s disease confirming that ranked URs aligned with the efficacy of existing drugs targeting the URs in the respective diseases Furthermore experimental validation included targeting the top ranked regulatory gene in SAR which was more effective than previously discovered IL4 inhibition Paper III While Paper I established the use of transcriptomic data for therapeutic predictions it focused on overlapping disease related changes across multiple inflammatory diseases and considered transcriptomic changes in only one cell type Paper II indicated a

potential benefit in UR prioritization in numerous cell types However it yielded heterogeneous results and was limited by the fact that few drugs directly target URs Neither of these approaches was feasible for individualized drug predictions Drawing on previous insights by us and others we next aimed to develop digital disease models for individual patients termed digital twins with the capability for drug efficacy screening We proposed scDrugPrio a strategy utilizing single cell scRNA sequencing based multicellular disease models incorporating key biological and pharmacological properties such as varying gene expression levels varying gene interactions within and between cell types and drug effect scDrugPrio was constructed based on a mouse model of arthritis and validated by improved precision recall for known drugs and in vitro studies of predicted drugs that were FDA approved for other diseases and had not yet been tried in rheumatoid arthritis or mouse arthritis For validation scDrugPrio was applied to human multiple sclerosis as well as Crohn s disease data that included tissue samples from healthy and sick tissue of all patients scDrugPrio was able to identify relevant treatments for individual patients and could distinguish anti TNF responders from non responders Conclusion This thesis demonstrates a framework for constructing digital disease models for personalized therapeutic predictions that might hold potential for better clinical treatment decisions By leveraging advanced genome wide analyses and network based approaches we may enhance the precision and efficacy of treatments for immune mediated inflammatory diseases bringing personalized medicine closer to clinical reality *Metal-Containing Polymeric Systems* John E. Sheats,Charles E. Carraher Jr.,Charles U. Pittman,2012-12-06 Research on metal containing polymers began in the early 1960 s when several workers found that vinyl ferrocene and other vinylic transition metal u com plexes would undergo polymerization under the same conditions as conventional organic monomers to form high polymers which incorporated a potentially reactive metal as an integral part of the polymer structures Some of these materials could act as semi conducters and pos sessed one or two dimensional conductivity Thus appli cations in electronics could be visualized immediately Other workers found that reactions used to make simple metal chelates could be used to prepare polymers if the ligands were designed properly As interest in homo geneous catalysts developed in the late 60 s and early 70 s several investigators began binding homogeneous catalysts onto polymers where the advantage of homo geneous catalysis known reaction mechanisms and the advantage of heterogeneous catalysis simplicity and ease of recovery of catalysts could both be obtained Indeed the polymer matrix itself often enhanced the selectivity of the catalyst
