The Second World War introduced the world to nuclear weapons and their consequences. Behind the scene of these nuclear weapons and an aspect of their consequences is radioactive waste. Radioactive waste has varying degrees of harmfulness and poses a problem when it comes to storage and disposal. Radioactive waste is usually kept below ground in varying containers which depend on how radioactive the waste is. High level radioactive waste (HLW) can be stored in underground carbon steel tanks. However, radioactive waste must also be further immobilized to ensure our safety. There are several sites in the United States where high level radioactive waste (HLW) are stored, including the Savannah River Site (SRS) established in 1950 to produce plutonium and tritium isotopes for defense purposes. In order to further immobilize the radioactive waste at this site, an in-tank precipitation (ITP) process is utilized. Through this method, the sludge portion of the tank wastes is being removed and immobilized in borosilicate glass for eventual disposal in a geological repository. As a result, a highly alkaline salt, present in both liquid and solid forms, is produced. The salt contains cesium, strontium, actinides such as plutonium and neptunium, and other radionuclides. But is this the best method? The National Research Council (NRC) has empaneled a committee at the request of the U.S. Department of Energy (DOE) to provide an independent technical review of alternatives to the discontinued in-tank precipitation (ITP) process for treating the HLW stored in tanks at the SRS. *Alternatives for High Level Waste Salt Processing at the Savannah River Site* summarizes the findings of the committee, which sought to answer 4 questions, including: Was an appropriately comprehensive set of cesium partitioning alternatives identified, and are there other alternatives that should be explored? Are there significant barriers to the implementation of any of the preferred alternatives, taking into account their state of development and their ability to be integrated into the existing SRS HLW system?

The U.S. Department of Energy (DOE) is nearing a decision on how to process 30 million gallons of high level radioactive waste salt solutions at the Savannah River Site in South Carolina to remove strontium, actinides, and cesium for immobilization in glass and eventual shipment to a geologic repository. The department is sponsoring research and development to evaluate the progress and results of the research and development work that is being undertaken on these candidate processes and assess whether the technical uncertainties have been sufficiently resolved to proceed with downsizing the list of candidate processes. Responses to the last two points are provided in this report.

the Savannah River Site focuses exclusively on the technical issues related to the candidate processes for radionuclide removal from high level waste salt solutions at SRS The committee's interim report served as a response to the first point of this charge and may be read in Appendix B In that report the committee found that DOE's proposed criteria are an acceptable basis for selecting among the candidate processes under consideration but that the criteria should not be implemented in a way that relies on a single numerical total score
