

INTRODUCTION

In case of circuit having pure resistance only with direct current source, the current reaches its steady state value almost instantaneously. But when capacitor and inductor are part of the circuit, it takes some time. As capacitor is charged, it opposes the flow of current and similarly any change in current is opposed by the inductor.

R - C CIRCUIT

2.1 CHARGING OF A CAPACITOR

The circuit diagram for charging and discharging a capacitor is given here. A resistor R and a capacitor C are connected with a double throw switch, by which the battery V can be connected in the circuit.

Initially, the capacitor is uncharged. When the switch is thrown to include the battery in the circuit, charge flows to the capacitor through the resistance R . This is called the charging current. The current continues till the voltage V_{db} across the capacitor is equal to the voltage V of the battery. If during the charging process the instantaneous current is i at an instant as shown, and the potential difference between a and d , and that between d and b are V_{ad} and V_{db} respectively, then

$$V_{ad} = iR \text{ and } V_{db} = \frac{q}{C}$$

where q is the charge on the capacitor at that instant

$$V_{ab} = V = V_{ad} + V_{db} = iR + \frac{q}{C}$$

where V is the constant voltage of the battery.

$$i = \frac{V}{R} - \frac{q}{RC}$$

Initially, as soon as the connection is made there is a current $i_0 = \frac{V}{R}$, since the charge on the capacitance is zero

As the charging continues, q increases and i decreases and finally becomes zero. At that time,

$$\frac{V}{R} - \frac{q}{RC} = 0$$

$q = CV = Q_0$, where Q_0 is the final charge on the capacitor.

In equation (iii), i may be written as $\frac{dq}{dt}$, so

$$\frac{dq}{dt} = \frac{V}{R} - \frac{q}{RC}$$
