Longitudinal effects of solanezumab over 80 weeks were explored, controlling for patient and caregiver baseline characteristics.**Results:** Caregivers rated patients' QOL worse than did patients themselves. Patients' QOL was correlated, albeit modestly, with clinical/health measures. Patients' QOL changed minimally over 80 weeks, although a treatment effect of solanezumab on QOL was detected.**Discussion:** Further investigations are needed to determine the optimal measures with which to quantify and quality QOL of patients with mild AD.© 2016 Eli Lilly and Company. 1. Introduction

Alzheimer's disease (AD) is a progressive neurodegenerative disease that is usually characterized by an initial gradual decline in the ability to remember new information, followed by deterioration of additional aspects of memory and other areas of cognition such as language, planning, and organization [1].

Given the wide range of cognitive and functional impairment levels represented across the spectrum of this progressive disease, one of the biggest challenges for clinical trial research in AD is the selection of appropriate measurable outcomes for determining treatment effects. This challenge is exacerbated by the fact that, even early in the disease course, AD is sometimes characterized by decreased insight that impairs the person's

ability to understand the impact of their disease on daily functioning [2], a clinical phenomenon known as anosognosia. Indeed, awareness of memory impairment begins to rapidly decline 2–3 years before the onset of dementia [2], suggesting that patient recall is of limited value in patients with AD. Therefore, caregiver reports and performance-based measures of cognition for patients are used for many clinical trials.

Clinical trials use outcomes designed to track progression of the disease, such as the Mini-Mental State Examination (MMSE) [3] and the Alzheimer's Disease Assessment Scale–Cognitive subscale (ADAS-Cog) [4], which measure cognitive function; the Neuropsychiatric Inventory (NPI) [5], which assesses psycho-behavioral symptomatology (and its brief form, the NPI-Q [6]); and measures of activities of daily living (ADL) such as the Alzheimer's Disease Cooperative Study–ADL Inventory (ADCS-ADL) [7].

In addition to clinical measures of disease progression, clinicians and others want to understand the clinical
