

Comparison of automated procedures for ARMA model identification

TETIANA STADNYTSKA, SIMONE BRAUN, AND JOACHIM WERNER
University of Heidelberg, Heidelberg, Germany

This article evaluates the performance of three automated procedures for ARMA model identification commonly available in current versions of SAS for Windows: MINIC, SCAN, and ESACF. Monte Carlo experiments with different model structures, parameter values, and sample sizes were used to compare the methods. On average, the procedures either correctly identified the simulated structures or selected parsimonious nearly equivalent mathematical representations in at least 60% of the trials conducted. For autoregressive models, MINIC achieved the best results. SCAN was superior to the other two procedures for mixed structures. For moving-average processes, ESACF obtained the most correct selections. For all three methods, model identification was less accurate for low dependency than for medium or high dependency processes. The effect of sample size was more pronounced for MINIC than for SCAN and ESACF. SCAN and ESACF tended to select higher-order mixed structures in larger samples. These findings are confined to stationary nonseasonal time series.

Time series analysis deals with repeated and equally spaced observations on a single unit. Classical statistical techniques are no longer appropriate here because data points cannot be assumed independent and uncorrelated. One of the most widely employed procedures for time series data is the *autoregressive integrated moving-average* (ARIMA) approach proposed by Box and Jenkins (1970). Since Glass, Willson, and Gottman (1975) introduced the ARIMA technique to the social and behavioral sciences, this methodology has been increasingly employed in different research fields (Delcor, Cadopi, Delignières, & Mesure, 2002; Fortes, Ninot, & Delignières, 2005; McCleary & Hay, 1980; Ninot, Fortes, & Delignières, 2005; Velicer & Colby, 1997; Velicer & Fava, 2003; Wagenmakers, Farrell, & Ratcliff, 2004).

The idea behind the Box–Jenkins procedure is to infer the true data generating process from an observed time series. The ARIMA strategy is based on a three-step iterative cycle of model identification, model estimation, and diagnostic checks in model accuracy. (For detailed treatments of the technique, see Bowerman & O'Connell, 1993; Box, Jenkins, & Reinsel, 1994; Brockwell & Davis, 2002; and Makridakis, Wheelwright, & Hyndman, 1998.) *Model identification* step provides insight into properties of the underlying stochastic process of the variable under study. Once the process has been inferred, it can be used either to test some hypothesis about its generating mechanism, forecast future values of the series, or remove dependency from the data so that it meets assumptions of the general linear model, as in interrupted time series experiments. In the first two cases, accurate model selection is indispensable.

Especially in theory testing, where model identification represents the primary goal of the analysis, model mis-

specification implies serious conceptual consequences and should be omitted. For instance, autoregressive models are characteristic of behavior containing internal temporal regularity, whereas moving-average models are characteristic of systems depending on external and occasional events. Thus autoregressive patterns are typically found in the studies investigating addictive behaviors (Rosel & Elósegui, 1994; Velicer, Redding, Richmond, Greeley, & Swift, 1992; Velicer, Rossi, Diclemente, & Prochaska, 1996). For nonaddictive habits of occasional smokers or drinkers, however, moving-average models are more appropriate. Analyzing travel behavior of different population groups, Fraschini and Axausten (2001) found that autoregressive models predominated in the age classes between 35 and 65 years old, reflecting more regular behavior probably caused by fixed employment and a more settled lifestyle. In contrast, moving-average patterns were mainly identified for younger participants, indicating the predominance of external influences on subject behavior. According to Velicer and Fava (2003), three popular hypotheses concerning nicotine's role in maintaining smoking, such as the fixed effect, nicotine regulation, and multiple regulation models, imply competing ARIMA patterns.

When the goal of research is to determine the efficacy of a specific intervention, as in interrupted time series analysis, model identification represents an intermediate step serving to transform the data (Glass et al., 1975). Hence, accurate model selection is not crucial here. Several alternative procedures avoiding model identification have been proposed in the last three decades (Algina & Swaminathan, 1977, 1979; Crosbie, 1993; Gottman, 1981; McKnight, McKean, & Huitema, 2000; Simonson, 1977; Velicer & McDonald, 1984,

Pearson, B.A. Ogunnaike, 2012-12-06 Much has been written about the general difficulty of developing the models required for model based control of processes whose dynamics exhibit significant nonlinearity for further discussion and references see Chapter 1 In fact the development of these models stands as a significant practical impediment to widespread industrial application of techniques like nonlinear model predictive control NMPC whose linear counterpart has profoundly changed industrial practice One of the reasons for this difficulty lies in the enormous variety of nonlinear models different classes of which can be less similar to each other than they are to the class of linear models Consequently it is a practical necessity to restrict consideration to one or a few specific nonlinear model classes if we are to succeed in developing understanding and using nonlinear models as a basis for practical control schemes Because they represent a highly structured extension of the class of linear finite impulse response FIR models on which industrially popular linear MPC implementations are based this book is devoted to the class of discrete time Volterra models and a few other closely related nonlinear model classes The objective of this book is to provide a useful reference for researchers in the field of process control and closely related areas collecting a reasonably wide variety of results that may be found in different parts of the large literature that exists on the general

Principles of Neural Model Identification, Selection and Adequacy Achilleas Zapranis,Apostolos-Paul N. Refenes,2012-12-06 Neural networks have had considerable success in a variety of disciplines including engineering control and financial modelling However a major weakness is the lack of established procedures for testing mis specified models and the statistical significance of the various parameters which have been estimated This is particularly important in the majority of financial applications where the data generating processes are dominantly stochastic and only partially deterministic Based on the latest most significant developments in estimation theory model selection and the theory of mis specified models this volume develops neural networks into an advanced financial econometrics tool for non parametric modelling It provides the theoretical framework required and displays the efficient use of neural networks for modelling complex financial phenomena Unlike most other books in this area this one treats neural networks as statistical devices for non linear non parametric regression analysis
