Parameter Estimation Jer-Nan Juang, 2000 A nonlinear optimization algorithm for linear predictive speech coding was developed early that not only optimizes the linear model coefficients for the open loop predictor but does the optimization including the effects of quantization of the transmitted residual It also simultaneously optimizes the quantization levels used for each speech segment In this paper we present an improved method for initialization of this nonlinear algorithm and

demonstrate substantial improvements in performance In addition the new procedure produces monotonically improving speech quality with increasing numbers of bits used in the transmitted error residual Examples of speech encoding and decoding are given for 8 speech segments and signal to noise levels as high as 47 dB are produced As in typical linear predictive coding the optimization is done on the open loop speech analysis model Here we demonstrate that minimizing the error of the closed loop speech reconstruction instead of the simpler open loop optimization is likely to produce negligible improvement in speech quality The examples suggest that the algorithm here is close to giving the best performance obtainable from a linear model for the chosen order with the chosen number of bits for the codebook
