William Stewart Hoar

Control Of Fish Migration:

The Control of Fish Migration R.J.F. Smith, 2012-12-06 Fish migration is important and spectacular. Migratory fish gather energy in one portion of the environment and transport it to other areas where it often becomes available to humans or to other elements in the ecosystem. Migration brings fish into situations that allow easy harvest as they concentrate along migration routes. Their journeys also make them vulnerable to human interference at critical points along their route. Salmon, for example, may harvest plankton in the open ocean and transport that food energy to coastal and inland regions where it is captured by fisheries or deposited in inland streams and utilized by the flora and fauna of the region. These salmon are able to complete journeys of thousands of kilometers from their natal streams to oceanic feeding grounds and back to the same home streams, an accomplishment that strains our credibility. We now understand some of the timing and guiding stimuli used in these migrations and mechanisms can be logically proposed on the basis of the established abilities of fishes to account for the unexplained portions of the migrations. There is no single factor guiding these fish. Instead, they are dependent on the presence in their environment of a great variety of appropriate orienting and timing stimuli. These stimuli are vulnerable to human interference. The more widespread and easily available the information on these requirements, the more readily fish can be protected from such interference.

Control and Timing of Fish Migration William Stewart Hoar, 1953 Investigations of the physiological control of fish migration have been confined to anadromous and katadromous species. Progress might be more rapid if studies were conducted on species in which migration is not complicated by change of osmotic medium. Various mechanisms are involved in the downstream migration of juvenile salmon. Schooling species are active at night and swim near the surface. They are therefore displaced downstream shortly after hatching. Elevated temperatures and increased thyroid activity sometimes modify reactions to current and hasten downstream movement. Stream dwelling species are related to the bottom, showing territorial behaviour by day and inactivity at night. A distinct transformation occurs prior to seaward migration. One lake dwelling species, *Oncorhynchus nerka*, remains in fresh water initially because of its negative phototaxis and inactivity. It likewise undergoes a transformation before leaving the lake. The parr-smolt transformation involves morphological, biochemical, and ethological changes and is associated with increased endocrine activity. Seaward migration of other diadromous species is probably controlled by mechanisms similar to those of salmon. Increased activity in thyroid gland and gonads is frequently associated with the change in response to current which must occur when the feeding migration ceases and the spawning migration commences. Treatment with thyroid and gonadal hormones increases the activity of salmon. In most fish that migrate upstream, one or both of these hormones is implicated. Precise patterns of migration are dependent upon a delicate interrelationship between the fish and the cyclical changes in its environment.

Physiology and Ecology of Fish Migration Hiroshi Ueda, Katsumi Tsukamoto, 2013-08-07 Among the roughly 30 000 species of fish, migratory species account for only 165 species, but most of them are very important fisheries.
