

ISDN (Integrated Services Digital Network)

ISDN (Integrated Services Digital Network) is a system of digital phone connections that has been designed for sending voice, video, and data simultaneously over digital or ordinary phone lines, with a much faster speed and higher quality than an analog system can provide. ISDN is basically a set of protocol for making and breaking circuit switched connections as well as for advanced call features for the customers. ISDN is the international communication standard for data transmission along telephone lines and has transmission speeds up to 64 Kbps per channel.

The emergence of ISDN represents an effort to standardize subscriber services, user/network interfaces, and network and internetwork capabilities. ISDN applications include high-speed image applications, additional telephone lines in home to serve the telecommuting industry, high speed file transfer, and video-conferencing. Voice service is also an application for ISDN.

ISDN has become a relatively old technology, but it isn't obsolete. ISDN is a technology that is often used behind the scenes as a component of more recent technology.

How Integrated Services Digital Network Works?

ISDN is a broadband service provides end-to-end digital communication for high speed data supporting voice, video and multimedia applications. Broadband as compare to Baseband is a type of service that supports logical channels. ISDN BRI and ISDN PRI are two services of ISDN technology used worldwide.

The ISDN BRI (Basic Rate Interface) offers two B channels and one D channel (2B+D). BRI B-channel service operates at 64 kbps and is meant to carry user data; BRI D-channel service operates at 16 kbps and is meant to carry control and signalling information, although it can support user data transmission under certain circumstances. The D channel signalling protocol comprises Layers 1 through 3 of the OSI reference model. BRI also provides for framing control and other overhead, bringing its total bit rate to 192 kbps called isdn 2. The BRI physical-layer specification is ITU-T formerly the CCITT 1.430. ISDN PRI (Primary Rate Interface) service offers 23 B channels and one D channel in some regions like North America and Japan, yielding a total bit rate of 1544 kbps including the PRI D Channel runs at 64 kbps. In Europe, Australia, and the other parts of the world ISDN PRI provides 30 B channels plus one 64-kbps channel with a total interface rate of 2048 kbps called isdn 30. The physical-layer specification of PRI is ITU-T 1.431.

A technique called bipolar with eight-zero substitution technique is used to transfer calls through the data channels – the B channels – with the signalling channels (D channels) being exclusively used for call set up and management. Once the call had been set up, a 64 Kbit/s synchronous bidirectional B channel transfer the data between the ends, which lasts until the call ends. Theoretically, there can be as many calls as there are data channels, the choice of same or different end point not withstanding. Also, it is possible to multiplex a number of bearer channels (B channels) to produce a single higher bandwidth channel, using a process called B channel bonding.
